- Background

Why a new optimizer

- you may have heard scalac could be faster
- maintainability, upgradability of the current optimizer. Quote:

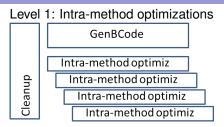

ŸJIRA							
Dashboards 👻	Projects	 Issues 					
Scala Programming Language / SI-7050 phase closelim is a mess							
∠ Edit	Assign	Assign To Me	Comment	More Actions +	Close Issue	Work	
> Details							
- Descrip	otion —						
elimination	. Second, it		elated things:	ness. First, it has bu copy propagation an			

The new backend, http://magarciaepfl.github.io/scala/

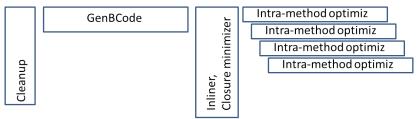

- makes the compiler 15% faster (uptime, also lowering CPU time)
- emits 10% more compact code (and that's without -neo:o1)
- documented
- ► future-proof (ASM-based, e.g. in view of Java 8)

- Background

Workflow of the new optimizer

Levels 2 and 3: Intra-program and Cross-libraries, resp.

Simplicity of each component contributes to overall simplicity

- Under the hood

- Bytecode emitter (GenBCode)

AST <code>ClassDef</code> node \rightarrow ASM <code>ClassNode</code> easier than expected:

CFG not necessary

just visit pre-order an expression node. Gist:

```
def genNormalMethodCall() {
    if (invokeStyle.hasInstance) { genLoadQualifier(fun) }
    genLoadArguments(args, paramTKs(app))
    // ASM visitMethodInsn(Opcodes.INVOKEVIRTUAL, owner, name, desc)
}
```

Additionally, not seen before features like:

more thorough outer-pointer elimination, https:

//github.com/magarciaEPFL/scala/commit/0a426b640411ee85983a6deb8a5612ebaa6d5ff3

- method handles, to cut down on anonymous-closure classes
- distinction between intra-program and cross-library inlining

- Under the hood

Intra-method optimizations

- Control-flow simplifications
 - collapse a multi-jump chain to target its final destination via a single jump
 - remove unreachable code
 - nullness propagation
- Propagation of known values
 - copy propagation
 - dead-store elimination
 - Preserve side-effects, but remove those (producer, consumer) pairs where the consumer is a DROP and the producer has its value consumed only by the DROP in question.
 - constant folding
 - eliding box/unbox pairs
 - eliding redundant local vars

Contrasting how the old and new optimizer tackle the same problem https://github.com/scala/scala/pull/2214

- Under the hood

More compact code

Just a few examples:

- method driver() in test/files/run/t7181.scala
 - 881 instructions, after -neo:o2 -closurify:delegating

4 ロ ト 4 日 ト 4 王 ト 4 王 ト 王 998 7/8

1004 instructions, with GenASM and -optimise

📜 UnoptLibByBCode.jar	6,473 KB
UnoptLibByICode.jar	6,746 KB

- Lessons learnt about speeding up the compiler

"Late Closure Classes" was the single largest contributor to the 15% speedup, because it results in less work for lambda lift, specialize, and erasure, among others.

```
/*
    Transform a function node (x_1, \ldots, x_n) \implies body
 *
    of type FunctionN[T_1, .., T_N, R] to a Block
 *
 *
      def hoisted(x 1: T 1, ..., x N: T n): R = body
 *
      hoisted(zeroes-for-params-above).asInstanceOf[AbstractFunctionN]
 *
 *
    The bytecode emitter will either:
 *
      (a) emit an anonymous closure class and its instantiation; or
 *
      (b) emit a method handle given as
 *
          constructor-argument to a closure instantiation.
 *
 */
def closureConversionModern(fun: Function): Tree = {
```
