Reaching Definitions

- ◆ Concept of *definition* and *use*
 - ◆ $a = x + y$
 - ◆ is a definition of a .
 - ◆ is a use of x and y .
- ◆ A **definition** reaches a **use** if value written by **definition** may be read by **use**.

Global Opt: Reaching Definitions

Advanced Compiler Techniques
<http://lamp.epfl.ch/teaching/advancedCompiler/>

Reaching Definitions and Constant Propagation

- ◆ Is a **use** of a variable a constant?
 - ◆ Check all reaching definitions.
 - ◆ If all assign variable to same constant.
 - ◆ Then use is in fact a constant.
- ◆ Can replace variable with constant.

Global Opt: Reaching Definitions & Constant Prop

3

Advanced Compiler Techniques
<http://lamp.epfl.ch/teaching/advancedCompiler/>

Computing Reaching Definitions

- ◆ Compute with sets of definitions:
 - ◆ Represent sets using bit vectors.
 - ◆ Each definition has a position in bit vector.
- ◆ At each basic block, compute:
 - ◆ Definitions that reach start of block.
 - ◆ Definitions that reach end of block.
- ◆ Do computation by simulating execution of program until the fixed point is reached.

Global Opt: Reaching Definitions

4

Advanced Compiler Techniques
<http://lamp.epfl.ch/teaching/advancedCompiler/>

Formalizing Analysis

- ◆ Each basic block has
 - ◆ **IN** - set of definitions that reach beginning of block
 - ◆ **OUT** - set of definitions that reach end of block
 - ◆ **GEN** - set of definitions generated in block
 - ◆ **KILL** - set of definitions killed in the block
- ◆ Compiler scans each basic block to derive **GEN** and **KILL** sets.

Global Opt: Reaching Definitions

5

Advanced Compiler Techniques
<http://lamp.epfl.ch/teaching/advancedCompiler/>

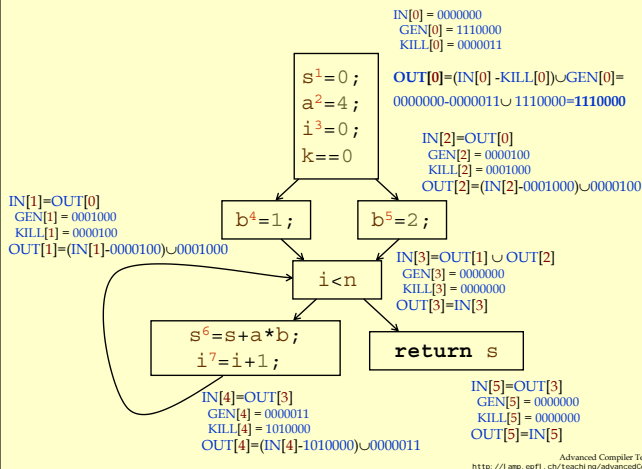

Dataflow Equations

- ◆ $IN[b_i] = OUT[b_1] \cup \dots \cup OUT[b_n]$
where b_1, \dots, b_n are predecessors of b_i
- ◆ $OUT[b_i] = (IN[b_i] - KILL[b_i]) \cup GEN[b_i]$
- ◆ $IN[entry] = 0000000$
- ◆ **Result**: system of equations.

Global Opt: Reaching Definitions

6

Advanced Compiler Techniques
<http://lamp.epfl.ch/teaching/advancedCompiler/>

Solving Equations

- ◆ Use fix point algorithm.
- ◆ Initialize with solution of $OUT[b_i] = 0000000$
- ◆ Repeatedly apply equations:
 - ◆ $IN[b_i] = OUT[b_1] \cup \dots \cup OUT[b_n]$
 - ◆ $OUT[b_i] = (IN[b_i] - KILL[b_i]) \cup GEN[b_i]$
- ◆ Until reach fixed point, i.e., until equation application has no further effect.
- ◆ Use a worklist to track which equation applications may have further effect.

Reaching Definitions Algorithm

```

for all nodes n2N
  OUT[n] = ;; // Or OUT[n] = GEN[n];
Changed = N; // N = all nodes in graph
while (Changed != ;;) // Until fixed point reached.
  choose n2Changed; // Node from worklist
  Changed = Changed - {n}; // Remove from worklist
  OldOut = OUT[n]; // Remember old result
  IN[n] = ;; // Calculate IN as join
  for all nodes p2predecessors(n) // of predecessors.
    IN[n] = IN[n] union OUT[p];
  OUT[n] = (IN[n] - KILL[n]) union GEN[n]; // Recalculate OUT
  if (OUT[n] != OldOut) // If OUT[n] changed
    for all nodes s2successors(n)
      Changed = Changed union {s}; // Add succs to worklist
  
```

Questions

- ◆ Does the algorithm halt?
 - ◆ yes, because transfer function is monotonic.
 - ◆ if increase IN, increase OUT.
 - ◆ in limit, all bits are 1.
- ◆ If bit is 1, is there always an execution in which corresponding definition reaches basic block?
- ◆ If bit is 0, does the corresponding definition ever reach basic block?
- ◆ Concept of conservative analysis.

Available Expressions

- ◆ An expression $x+y$ is available at a point p if
 - ◆ every path from the initial node to p evaluates $x+y$ before reaching p ,
 - ◆ and there are no assignments to x or y after the evaluation but before p .
- ◆ Available Expression information can be used to do global (across basic blocks) CSE.
- ◆ If an expression is available at use, there is no need to re-evaluate it.

Computing Available Expressions

- ◆ Represent sets of expressions using bit vectors.
- ◆ Each expression corresponds to a bit.
- ◆ Run dataflow algorithm similar to reaching definitions.
- ◆ Big difference:
 - ◆ Definition reaches a basic block if it comes from ANY predecessor in CFG.
 - ◆ Expression is available at a basic block only if it is available from ALL predecessors in CFG.

Expressions

- 1: $x+y$
- 2: $i < n$
- 3: $i+c$
- 4: $x==0$

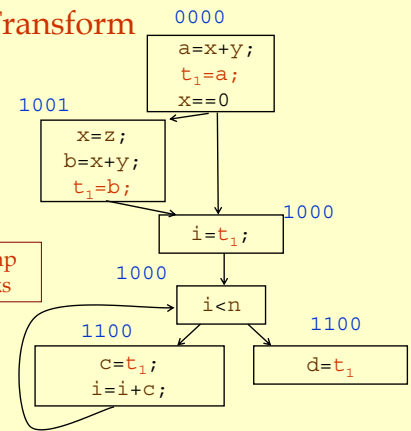

Global CSE Transform

Expressions

- 1: $x+y$
- 2: $i < n$
- 3: $i+c$
- 4: $x==0$

Must use same temp
for CSE in all blocks

Formalizing Analysis

- ◆ Each basic block has
 - IN - set of expressions that reach beginning of block.
 - OUT - set of expressions that reach end of block.
 - GEN - set of expressions generated in block.
 - KILL - set of expressions killed in the block.
- ◆ $GEN[x=z; b=x+y] = 1000$
- ◆ $KILL[x=z; b=x+y] = 1001$
- ◆ Compiler scans each basic block to derive GEN and KILL sets.

Dataflow Equations

- ◆ $IN[b_i] = OUT[b_1] \cap \dots \cap OUT[b_n]$
 - ◆ where b_1, \dots, b_n are predecessors of b_i
- ◆ $OUT[b_i] = (IN[b_i] - KILL[b_i]) \cup GEN[b_i]$
- ◆ $IN[entry] = 0000$
- ◆ **Result:** system of equations.

Solving Equations

- ◆ Use fix point algorithm.
- ◆ $IN[entry] = 0000$
- ◆ Initialize with solution of $OUT[b_i] = 1111$
- ◆ Repeatedly apply equations:
 - ◆ $IN[b_i] = OUT[b_1] \cap \dots \cap OUT[b_n]$
 - ◆ $OUT[b_i] = (IN[b_i] - KILL[b_i]) \cup GEN[b_i]$
- ◆ Use a worklist to track which equation applications may have further effect.

Available Expressions Algorithm

```

for all nodes n2N // E is set of all expressions.
  OUT[n] = E; // OUT[n] = E - KILL[n];
Changed = N; // N = all nodes in graph
while (Changed != ; )
  choose n2Changed;
  Changed = Changed - {n};
  IN[n] = E;
  OldOut = OUT[n]
  for all nodes p2predecessors(n)
    IN[n] = IN[n] & OUT[p];
  OUT[n] = (IN[n] - KILL[n]) & GEN[n];
  if (OUT[n] != OldOut)
    for all nodes s2successors(n) Changed = Changed & {s};

```

Questions

- ◆ Does algorithm always halt?
- ◆ If expression is available in some execution, is it always marked as available in analysis?
- ◆ If expression is not available in some execution, can it be marked as available in analysis?
- ◆ In what sense is the algorithm conservative?

Duality In Two Algorithms

- ◆ **Reaching definitions**
 - ◆ Confluence operation is set **union**.
 - ◆ **OUT**[b] initialized to **empty set**.
- ◆ **Available expressions**
 - ◆ Confluence operation is set **intersection**.
 - ◆ **OUT**[b] initialized to **set of available expressions**.
- ◆ General framework for dataflow algorithms.
- ◆ Build parameterized dataflow analyzer once, use for all dataflow problems.

20

Advanced Compiler Techniques
<http://lamp.epfl.ch/teaching/advancedCompiler/>

Liveness Analysis

- ◆ A variable v is live at point p if
 - ◆ v is used along some path starting at p , and
 - ◆ no definition of v along the path before the use.
- ◆ When is a variable v dead at point p ?
 - ◆ No use of v on any path from p to exit node, or
 - ◆ If all paths from p , redefine v before using v .

21

Advanced Compiler Techniques
<http://lamp.epfl.ch/teaching/advancedCompiler/>

What Use is Liveness Information?

- ◆ Register allocation.
 - ◆ If a variable is dead, we can reassign its register.
- ◆ Dead code elimination.
 - ◆ Eliminate assignments to variables not read later.
 - ◆ But must not eliminate last assignment to variable (such as instance variable) visible outside CFG.
 - ◆ Can eliminate other dead assignments.
 - ◆ Handle by making all externally visible variables live on exit from CFG.

22

Advanced Compiler Techniques
<http://lamp.epfl.ch/teaching/advancedCompiler/>

Conceptual Idea of Analysis

- ◆ Simulate execution.
- ◆ But start from exit and go **backwards** in CFG.
- ◆ Compute liveness information from end to beginning of basic blocks.

23

Advanced Compiler Techniques
<http://lamp.epfl.ch/teaching/advancedCompiler/>

Liveness Example

- ◆ Assume a, b, c visible outside function. They are live on exit.
- ◆ Assume x, y, z, t are not visible.
- ◆ Represent liveness using a bit vector: order is $abcxyz$.

24

Advanced Compiler Techniques
<http://lamp.epfl.ch/teaching/advancedCompiler/>

Using Liveness Information for Dead Code Elimination

- ◆ Assume a, b, c visible outside function. They are live on exit.
- ◆ Assume x, y, z, t are not visible.
- ◆ Represent liveness using a bit vector: order is $abcxyzt$.

Formalizing Analysis

- ◆ Each basic block has
 - IN** - set of variables live at start of block.
 - OUT** - set of variables live at end of block.
 - USE** - set of variables with upwards exposed uses in block. (**GEN**)
 - DEF** - set of variables defined in block. (**KILL**)
- ◆ $USE[x=z; x=x+1; y=1;] = \{z\}$ (x not in **USE**)
- ◆ $DEF[x=z; x=x+1; y=1;] = \{x, y\}$
- ◆ Compiler scans each basic block to derive **USE** and **DEF** sets.

Algorithm

```

OUT[Exit] = ;
IN[Exit] = USE[n];
for all nodes n ∈ N - {Exit}
  IN[n] = ;
  Changed = N - {Exit};
  while (Changed != ; )
    choose n ∈ Changed;
    Changed = Changed - {n};
    OldIn = IN[n];
    OUT[n] = ;
    for all nodes s ∈ successors(n)
      OUT[n] = OUT[n] ∪ IN[s];
    IN[n] = USE[n] ∪ (OUT[n] - DEF[n]);
    if (IN[n] != OldIn)
      for all nodes p ∈ predecessors(n)
        Changed = Changed ∪ {p};
  
```

Similar to Other Dataflow Algorithms

- ◆ Backwards analysis, not forwards.
- ◆ Still have transfer functions.
- ◆ Still have confluence operators.
- ◆ Can generalize framework to work for both forwards and backwards analyses.

Analysis Information Inside Basic Blocks

- ◆ One detail:
 - ◆ Given dataflow information at **IN** and **OUT** of node.
 - ◆ Also need to compute information at each statement of basic block.
 - ◆ Simple propagation algorithm usually works fine.
 - ◆ Can be viewed as restricted case of dataflow analysis.

Summary

- ◆ Dataflow Analysis
 - ◆ Control flow graph.
 - ◆ **IN**[b], **OUT**[b], transfer functions, join points.
- ◆ Pairs of analyses and transformations:
 - ◆ **Reaching definitions**/constant propagation.
 - ◆ **Available expressions**/common sub-expression elimination.
 - ◆ Liveness analysis/Dead code elimination.
