

Lists in Funnel

- Lists are sequences of values
- They are one of the most important data type for functional programming
- A lot of functional programming languages have lists as a built-in data type
- In Funnel, lists are not primitive and have to be encoded explicitly
- Funnel offers three ways for encoding compound data types
 - tuples
 - functions
 - records

Implementing Lists with Records

- Lists are represented as linked data structures
- We need two constructors:
 - Nil, for creating empty lists
 - Cons(x, xs), for creating a list with head x and tail xs
- We want every list to have the functions isEmpty, head and tail:

```
def Nil = {  
  def isEmpty = true  
  def head = error "Nil.head"  
  def tail = error "Nil.tail"  
}  
def Cons(x, xs) = {  
  def isEmpty = false  
  def head = x  
  def tail = xs  
}
```

Creating Lists

Here's a transcript of a *funny* session:

```
> val l = Cons(1, Cons(2, Cons(3, Nil)))
'val l = (<record id=10, adr=129, type=(isEmpty, head, tail)>)'
> (l.head, l.tail.head)
(1, 2)
> val l' = l.tail.tail
'val l' = (<record id=10, adr=129, type=(isEmpty, head, tail)>)'
> l'.head
3
> l'.tail.head
user abortion: "Nil.head"
```

Clients of the List Abstraction

Functions operating on lists use

- `isEmpty` for distinguishing empty lists from non-empty lists, and
- the projections `head` and `tail` for accessing the first element and the rest of the list for non-empty lists

Let's write a function `length` that computes the length of a given list:

```
def length(xs) = if (xs.isEmpty) 0 else 1 + length(xs.tail)
```

The implementation of `append`, which concatenates two lists is similar:

```
def append(xs, ys) = if (xs.isEmpty) ys  
                    else Cons(xs.head, append(xs.tail, ys))
```

Example

Suppose we want to sort a list of numbers into ascending order:

- One way to sort the list [7, 3, 9, 2] is to sort the tail [3, 9, 2] to give [2, 3, 9].
- It is then a matter of inserting the head 7 in the right place to give the result [2, 3, 7, 9]

This idea describes *Insertion Sort*:

```
def isort(xs) = if (xs.isEmpty) Nil
               else ins(xs.head, isort(xs.tail))
```

How does an implementation of the missing function `ins` look like?

Patterns of Computation

- The examples show that functions over lists often have similar structures
- We can identify several patterns of computation like
 - Transform every element of a list in some way
 - Combine the elements of a list using some operator
- Functional programming languages enable programmers to write general functions which implement patterns like this
- These functions are *higher-order functions* which get a transformation or an operator as one argument

Combining Lists

- We introduced already the function `append` for list concatenation
- Function `concat` concatenates all lists contained in another list:

```
def concat(xss) = if (xss.isEmpty) Nil
                  else append(xss.head, concat(xss.tail))
```

Example: `concat[[1,2], [], [3]] = [1, 2, 3]`

- `zip` combines two lists into a list of pairs:

```
def zip(xs, ys) = if (xs.isEmpty || ys.isEmpty) Nil
                  else Cons((xs.head, ys.head),
                             zip(xs.tail, ys.tail))
```

Example:

```
zip(["Frank", "Bill"], [1, 2]) = [("Frank", 1), ("Bill", 2)]
```

Combining Lists

- A more general form of `zip` is function `zipwith`. It applies a function `f` to corresponding elements from two lists:

```
def zipwith(f, xs, ys) = if (xs.isEmpty || ys.isEmpty) Nil
                        else Cons(f(xs.head, ys.head),
                                zipWith(xs.tail, ys.tail))
```

- Example: you have a list of first names `fn` and a list of surnames `sn`. You can create a list of full names easily using `zipwith`:

```
zipwith((first, last) => first + " " + last, fn, sn)
```

Applying to All (mapping)

Many functions call for all of the elements of a list to be transformed in some way – this we call *mapping*.

Example: Suppose we have a list of tuples (Name, Age) and we want to convert this list into a list of names only:

```
def names(xs) = {  
  if (xs.isEmpty) Nil  
  else { val (name, age) = xs.head; Cons(name, names(xs.tail)) }  
}
```

Instead of implementing this scheme with different transformations over and over again, we can write a *single map* function, which applies a function **f** to all elements of a list:

```
def map(f, xs) = if (xs.isEmpty) Nil  
                else Cons(f(xs.head), map(f, xs.tail))
```

Selecting Elements (filtering)

Selecting all the elements of a list with a given property is also common:

```
def odds(xs) = if (xs.isEmpty) Nil
              else if ((xs.head % 2) == 0) odds(xs.tail)
              else Cons(xs.head, odds(xs.tail))
```

The general function `filter` takes a property and a list and returns those elements of the list having the property.

Properties are modelled as predicates; i.e. functions over element types that return a boolean value.

```
def filter(p, xs) = if (xs.isEmpty) Nil
                  else if (!p(xs.head)) filter(p, xs.tail)
                  else Cons(xs.head, filter(p, xs.tail))
```

With `filter`, function `odds` can be rewritten in the following way:

```
def odds(xs) = filter((x | (x % 2) == 1), xs)
```

Combining Items (folding)

- Most list operations we saw return lists as their result
- The operation of *folding* an operator or function into a list of values is more general, since it can transform lists into other types
- There are two ways of folding a function into a list:

$$\text{foldr}(f, a, [x_1, x_2, \dots, x_n]) = f(x_1, f(x_2, \dots f(x_n, a)))$$

$$\text{foldl}(f, a, [x_1, x_2, \dots, x_n]) = f(\dots f(f(a, x_1), x_2), \dots, x_n)$$

- Here's a Funnel implementation:

```
def foldr(f, a, xs) = if (xs.isEmpty) a
                    else f(xs.head, foldr(f, a, xs.tail))
def foldl(f, a, xs) = if (xs.isEmpty) a
                    else foldl(f, f(a, xs.head), xs.tail)
```

Applying Fold

Let's implement a function that calculates the sum of all numbers of a list using the `fold` combinator:

```
def sum(xs) = foldr((x, y) => x + y, 0, xs)
```

Encoding the function `append` is simple as well:

```
def append(xs, ys) = foldr(Cons, ys, xs)
```

Is it possible to use `foldl` for both examples? What about efficiency?

A More Complicated Example

This is an obvious solution for reversing a list:

```
def reverse(xs) = if (xs.isEmpty) Nil
                  else append(reverse(xs.tail), Cons(xs.head, Nil))
```

Can you implement a more efficient version using the `fold` combinator?

Breaking up Lists

Another common pattern is to take or drop items from a list while they have some property.

`take` returns the first `n` elements of a list, `drop` returns the list without the first `n` elements:

```
def take(n, xs) = if (n > 0) Cons(xs.head, take(n-1, xs.tail)) else Nil
def drop(n, xs) = if (n > 0) drop(n - 1, xs.tail) else xs
```

`takewhile` returns the longest prefix of a list, where every argument satisfies a predicate `p`:

```
def takewhile(p, xs) = if (xs.isEmpty || !p(xs.head)) Nil
                    else Cons(xs.head, takewhile(p, xs.tail))
```

`dropwhile` is implemented similarly.

Exercises

In functional programming languages, matrices are often implemented as lists of rows, where each row is itself a list of values. The matrix

$$\begin{pmatrix} x_{1,1} & x_{1,2} & x_{1,3} \\ x_{2,1} & x_{2,2} & x_{2,3} \end{pmatrix}$$

would be encoded like this:

$$[[x_{1,1}, x_{1,2}, x_{1,3}], [x_{2,1}, x_{2,2}, x_{2,3}]]$$

Implement the following functions operating on matrices and vectors:

- `scalarprod` computes the scalar product of two vectors
- `transpose` transposes a given matrix
- `add` adds two matrices
- `mult` multiplies two matrices

A list type is supplied, so all important list operations can be used.

Modules in Funnel

- To avoid name space conflicts, new data types are best implemented inside of a module.
- A module is a record consisting of all the constructors
- Example:

```
val List = {  
  def Nil = {  
    def isEmpty = true  
    def head = error "Nil.head"  
    def tail = error "Nil.tail"  
  }  
  def Cons = {  
    def isEmpty = false  
    def head = x  
    def tail = xs  
  }  
}
```

Modules in Funnel

- Access to the constructors has to be qualified with `List`:

```
List.Cons(1, List.Cons(2, List.Cons(3, List.Nil)))
```
