

Foundations of Software

Martin Odersky, EPFL

Slides in part adapted from:
University of Pennsylvania CIS 500: Software Foundations - Fall 2006
by Benjamin Pierce

1

Course Overview

2

What is “software foundations”?

Software foundations (or “theory of programming languages”) is the mathematical study of the **meaning** of programs.

The goal is finding ways to describe program behaviors that are both **precise** and **abstract**.

- ▶ **precise** so that we can use mathematical tools to formalize and check interesting properties
- ▶ **abstract** so that properties of interest can be discussed clearly, without getting bogged down in low-level details

3

Why study software foundations?

- ▶ To prove specific properties of particular programs (i.e., program verification)
 - ▷ Important in some domains (safety-critical systems, hardware design, security protocols, inner loops of key algorithms, ...), but still quite difficult and expensive
- ▶ To develop intuitions for *informal* reasoning about programs
- ▶ To prove general facts about all the programs in a given programming language (e.g., safety or isolation properties)
- ▶ To understand language features (and their interactions) deeply and develop principles for better language design
(PL is the “materials science” of computer science...)

4

What you can expect to get out of the course

- ▶ A more sophisticated perspective on programs, programming languages, and the activity of programming
 - ▷ How to view programs and whole languages as formal, mathematical objects
 - ▷ How to make and prove rigorous claims about them
 - ▷ Detailed study of a range of basic language features
- ▶ Deep intuitions about key language properties such as type safety
- ▶ Powerful tools for language design, description, and analysis

Most software designers are language designers!

5

What this course is not

- ▶ An introduction to programming
- ▶ A course on functional programming (though we'll be doing some functional programming along the way)
- ▶ A course on compilers (you should already have basic concepts such as lexical analysis, parsing, abstract syntax, and scope under your belt)
- ▶ A comparative survey of many different programming languages and styles

6

Approaches to Program Meaning

- ▶ **Denotational semantics** and **domain theory** view programs as simple mathematical objects, abstracting away their flow of control and concentrating on their input-output behavior.
- ▶ **Program logics** such as **Hoare logic** and **dependent type theories** focus on logical rules for reasoning about programs.
- ▶ **Operational semantics** describes program behaviors by means of abstract machines. This approach is somewhat lower-level than the others, but is extremely flexible.
- ▶ **Process calculi** focus on the communication and synchronization behaviors of complex concurrent systems.
- ▶ **Type systems** describe approximations of program behaviors, concentrating on the shapes of the values passed between different parts of the program.

7

Overview

This course will concentrate on operational techniques and type systems.

- ▶ Part I: Modeling programming languages
 - ▷ Syntax and parsing
 - ▷ Operational semantics
 - ▷ Inductive proof techniques
 - ▷ The lambda-calculus
 - ▷ Syntactic sugar; fully abstract translations
- ▶ Part II: Type systems
 - ▷ Simple types
 - ▷ Type safety
 - ▷ References
 - ▷ Subtyping

8

Overview

- ▶ Part III: Object-oriented features (case study)
 - ▷ A simple imperative object model
 - ▷ An analysis of core Java
 - ▷ An analysis of core Scala

9

Organization of the Course

10

People

Instructor: Martin Odersky
 INR 319
 <martin.odersky@epfl.ch>

Teaching Assistants: Philipp Haller
 <philipp.haller@epfl.ch>
 Iulian Dragos
 <iulian.dragos@epfl.ch>

11

Information

Textbook: Types and Programming Languages,
 Benjamin C. Pierce, MIT Press, 2002

Webpage: http://lampwww.epfl.ch/teaching/foundations_of_software/

12

Elements of the Course

- ▶ The Foundations of Software course consists of
 - ▷ lecture (Tuesday 10:15-12:00, room INM 201)
 - ▷ exercises and project work (Wednesday 10:15-12:00, rooms CO 020, CO 121)
- ▶ The lecture will follow in large parts the textbook.
- ▶ For lack of time, we cannot treat all essential parts of the book in the lectures, that's why the [textbook is required reading](#) for participants of the course.

13

Homework and Projects

You will be asked to

- ▶ solve and hand in some written exercise sheets,
- ▶ do a number of programming assignments, including
 - ▷ parsers,
 - ▷ interpreters and reduction engines,
 - ▷ type checkersfor a variety of small languages.
- ▶ The recommended implementation language for these assignments is [Scala](#).

14

Scala

- ▶ Scala is a functional and object-oriented language that is closely interoperable with Java.
- ▶ It is very well suited as an implementation language for type-checkers, in particular because it supports:
 - ▷ pattern matching,
 - ▷ higher-order functions,
 - ▷ inheritance and mixins.

15

Learning Scala

If you don't know Scala yet, there's help:

- ▶ The Scala web site:
www.scala-lang.org
- ▶ On this site, the documents:
 - ▷ *A Brief Scala Tutorial - an introduction to Scala for Java programmers.* (short and basic).
 - ▷ *An Introduction to Scala* (longer and more comprehensive).
 - ▷ *An Overview of the Scala Programming Language* (high-level).
 - ▷ *Scala By Example* (long, comprehensive, tutorial style).
- ▶ The assistants.

16

Grading and Exams

Final course grades will be computed as follows:

- ▶ Homework and project: 30%
- ▶ Mid-term exam: 30%
- ▶ Final exam: 40%

Exams:

1. Mid-term: Tue, Nov 11th, 2008
2. Final exam: to be announced

(dates are provisional)

17

Collaboration

- ▶ Collaboration on homework is **strongly encouraged**.
- ▶ Studying with other people is the best way to internalize the material
- ▶ Form pair programming and study groups!
2-3 people is a good size. 4 is too many for all to have equal input.

"You never really misunderstand something
until you try to teach it...
" – Anon.

18

Plagiarism

- ▶ A single group will of course share code.
- ▶ But plagiarizing **code** by **other groups** as part of a project is unethical and will not be tolerated, whatever the source.

19

Part I

Modelling programming languages

20

Syntax and Parsing

- ▶ The first-level of modeling a programming language concerns its [context-free syntax](#).
- ▶ Context free syntax determines a set of legal [phrases](#) and determines the [\(tree-\)structure](#) of each of them.
- ▶ It is often given on two levels:
 - ▷ [concrete](#): determines the exact (character-by-character) set of legal phrases
 - ▷ [abstract](#): concentrates on the tree-structure of legal phrases.
- ▶ We will be mostly concerned with abstract syntax in this course.
- ▶ But to be able to write complete programming tools, we need a convenient way to map character sequences to trees.

21

Approaches to Parsing

There are two ways to construct a parser:

- ▶ [By hand](#) Derive a parser program from a grammar.
- ▶ [Automatic](#) Submit a grammar to a tool which generates the parser program.

In the second approach, one uses a special [grammar description language](#) to describe the input grammar.

22

Domain-Specific Languages

- ▶ The grammar description language is an example of a [domain-specific language \(DSL\)](#).
- ▶ The parser generator acts as a processor ("[compiler](#)") for this language — that's why it's sometimes called grandly a "[compiler-compiler](#)".
- ▶ Example of a "program" in the grammar description DSL:

```
Expr ::= Term { '+' Term | '-' Term }.
Term  ::= Factor { '*' Factor | '/' Factor }.
Factor ::= Number | '(' Expr ')'
```

23

Hosted Domain Specific Languages

- ▶ An alternative to a stand-alone DSL is a [hosted DSL](#).
- ▶ Here, the DSL does not exist as a separate language but as an API in a [host language](#).
- ▶ The host language is usually a general purpose programming language.

We will now develop this approach for grammar description languages.

24

A Hosted Grammar Description Language in Scala

We will develop a framework where grammars can be described like this:

```
def expr : Parser[Any] = term ~ rep("+", ~ term | "-", ~ term)
def term : Parser[Any] = factor ~ rep(" * ", ~ factor | "/" ~ factor)
def factor : Parser[Any] = "(" ~ expr ~ ")" | numericLit
```

This description can be produced from the previous grammar by systematic text replacements:

- ▶ Insert a `def` at the beginning of each production.
- ▶ The `::=` becomes `: Parser[Any] =`.
- ▶ Sequential composition is now expressed by a `~`.
- ▶ Repetition `{...}` is now expressed by `rep(...)`.
- ▶ Option `[...]` is now expressed by `opt(...)`.

25

- ▶ The point at the end of a production is removed.

26

Parser Combinators

- ▶ The differences between Grammar A and Grammar B are fairly minor.
(Note in particular that existing DSL's for grammar descriptions also tend to add syntactic complications to the idealized Grammar A we have seen).
- ▶ The important difference is that Grammar B is a valid Scala program, when combined with an API that defines the necessary primitives.
- ▶ These primitives are called `parser combinators`.

27

The Basic Idea

For each language (identified by grammar symbol S), define a function f_S that, given an input stream i ,

- ▶ if a prefix of i is in S , return `Success(Pair(x, i'))` where x is a result for S and i' is the rest of the input.
- ▶ otherwise, return `Failure(msg, i)` where `msg` is an error message string.

The first behavior is called `success`, the second `failure`.

28

The Basic Idea in Code

Assume:

```
class StandardTokenParsers {  
  type Parser = Input => ParseResult
```

where

```
type Input = Reader[Token] // a stream of Tokens with positions.
```

and we assume a class `Token` with subclasses

- ▶ `case class Keyword(chars: String)` for keywords,
- ▶ `case class NumericLit(chars: String)` for numbers,
- ▶ `case class StringLit(chars: String)` for strings,
- ▶ `case class Identifier(chars: String)` for identifiers.

In each case, `chars` represents the characters making up the token.

29

Also assume a class `ParseResult[T]` with subclasses

```
case class Success[T](result: T, in: Input)  
extends ParseResult[T]  
  
case class Failure(msg: String, in: Input)  
extends ParseResult[Nothing]
```

30

Object-Oriented Parser Combinators

- ▶ In fact, we will also need to express `|` and `~` as methods of parsers.
- ▶ That's why we extend the function type of parsers as follows:

```
abstract class Parser[T] extends (Input => ParseResult[T]) {  
  // An unspecified method that defines the parser function.  
  def apply(in: Input): ParseResult  
  
  // A parser combinator for sequential composition  
  def ~ ...  
  
  // A parser combinator for alternative composition  
  def | ...  
}
```

It remains to define concrete combinators that implement this class (see below).

31

A Generic Single-Token Parser

- ▶ The following parser succeeds if the first token in the input satisfies a given predicate `p`.^a

- ▶ If it succeeds, it reads the token string and returns it as a result.

```
def token(kind: String)(p: Token => boolean) = new Parser[String] {  
  def apply(in: Input) =  
    if (p(in.head)) Success(in.head.chars, in.tail)  
    else Failure(kind+" expected", in)  
}
```

^aThis is somewhat of a simplification; the actual framework contains an `elem` parser instead which returns the token itself

32

Specific Single-Token Parsers

- ▶ The following parser succeeds if the first token in the input is a given keyword “chars”:
- ▶ If it succeeds, it returns a keyword token as a result.

```
implicit def keyword(chars: String) = token("'" + chars + "'") {  
  case Keyword(chars1) => chars == chars1  
  case _ => false  
}
```

- ▶ Note that `keyword` is defined `implicit`. This means we can usually just write (e.g.) `"if"` for `keyword("if")`.

33

- ▶ The following parsers succeed if, respectively, the first token in the input is a numeric or string literal, or an identifier.

```
def numericLit = token("number")(_._isInstanceOf[NumericLit])  
def stringLit = token("string literal")(_._isInstanceOf[StringLit])  
def ident = token("identifier")(_._isInstanceOf[Identifier])
```

34

The Sequence Combinator

- ▶ The sequence combinator $P \sim Q$ succeeds if P and Q both succeed. It then returns a list containing the concatenation of result of P and the result of Q .
- ▶ \sim is implemented as a method of class `Parser`.

```
abstract class Parser[T] {  
  def ~ [U](q: Parser[U]) = new Parser[T ~ U] {  
    def apply(in: Input) = Parser.this(in) match {  
      case Success(x, in1) =>  
        q(in1) match {  
          case Success(y, in2) => Success(new ~(x, y), in2)  
          case failure => failure  
        }  
      case failure => failure  
    }  
  }  
}
```

35

Concatenating Results

Normally, the \sim combinator returns a the results of the two parsers that are run sequentially wrapped in a \sim -object.

Here \sim is also case class that concatenates two results

```
case class ~(T, U)(_1: T, _2: U) {  
  override def toString = "(" + _1 + " ~ " + _2 + ")"  
}
```

(one could have also used a pair for this, but \sim turns out to be nicer – see below).

There are also two variants of \sim which return only the left or only the right operand:

```
P <~ Q // returns only result of P  
P ~> Q // returns only result of Q
```

36

The Alternative Combinator

- ▶ The alternative combinator $P \mid Q$ succeeds if either P or Q succeeds.
- ▶ It returns the result of P if P succeeds, or the result of Q , if Q succeeds.
- ▶ The alternative combinator is implemented as a method of class `Parser`.

```
def | (q: => Parser[T]) = new Parser[T] {  
  def apply(in: Input) = Parser.this(in) match {  
    case s1 @ Success(_, _) => s1  
    case failure => q(in)  
  }  
}
```

37

Failure And Success Parsers

- ▶ The parser `failure(msg)` always fails with the given error message. It is implemented as follows:

```
def failure(msg: String) = new Parser[Nothing] {  
  def apply(in: Input) = Failure(msg, in)  
}
```

- ▶ The parser `success(result)` always succeeds with the given result. It does not consume any input. It is implemented as follows:

```
def success[T](result: T) = new Parser[T] {  
  def apply(in: Input) = Success(result, in)  
}
```

38

Result Conversion

The parser $P \wedge f$ succeeds iff P succeeds. In that case it returns the result of applying f to the result of P .

```
def ^^ [U](f: T => U) = new Parser[U] {  
  def apply(in: Input) = Parser.this(in) match {  
    case Success(x, in1) => Success(f(x), in1)  
    case f => f  
  }  
}
```

A variant $\wedge\wedge$ takes a value V as right hand side argument.

It returns V if the left hand parser succeeds:

```
def ^^ [U](r: U): Parser[U] = ^^ (x => r)
```

39

Option and Repetition Combinators

- ▶ The `opt(P)` combinator always succeeds and returns an `Option` result. It returns `Some(R)` iff P succeeds with R , and it returns `None` if P fails.
- ▶ The `rep(P)` combinator applies P zero or more times until P fails. It returns a list of all results returned by P .

The two combinators are implemented as follows:

```
def opt[T](p: Parser[T]): Parser[Option[T]] =  
  p ^^ Some | success(None)  
def rep[T](p: Parser[T]): Parser[List[T]] =  
  p ~ rep(p) ^^ { case x ~ xs => x :: xs } | success(List())
```

Note that neither of these combinators can fail!

40

The Interleaved Repetition Combinator

The `repsep(P, Q)` parser parses a (possibly empty) sequence

$P Q P \dots Q P$

It returns a list of all results returned by P .

Example: `repsep(ident, ",")` parses a list of identifiers separated by commas.

The `repsep` combinator is implemented as follows:

```
def repsep[T, U](p: Parser[T], q: Parser[U]): Parser[List[T]] =  
  p ~ rep(q ~> p) ^^ { case r ~ rs => r :: rs } | success(List())
```

41

Other Combinators

More combinators can be defined if necessary.

Exercise: Implement the `rep1(P)` parser combinator, which applies P one or more times.

Exercise: Define `opt` and `rep` directly, without making use of `~`, `|`, and `empty`.

42

An Example: JSON

JSON, or JavaScript Object Notation, is a popular data interchange format.

JSON data essentially consists of objects `{...}`, arrays `[...]`, numbers, and strings.

Here is an example of a JSON value:

```
{ "address book": {  
  "name": "John Smith",  
  "address": { "street": "10 Market Street",  
               "city"  : "San Francisco, CA",  
               "zip"   : 94111 },  
  "phone numbers": ["408 338-4238", "408 111-6892"]  
}
```

43

A JSON parser

```
package examples.parsing  
  
// import the standard parser class  
import scala.util.parsing.combinator1.syntactical.StandardTokenParsers  
  
object JSON extends StandardTokenParsers {  
  
  // fix some delimiter symbols ...  
  lexical.delimiters += ("{" , "}", "[", "]", ":", ";")  
  // ... and some reserved words  
  lexical.reserved += ("null", "true", "false")  
  
  // here are the four productions making up the JSON grammar  
  def obj  : Parser[Any] = "{" ~ repsep(member, ",") ~ "}"  
  def arr  : Parser[Any] = "[" ~ repsep(value, ",") ~ "]"  
  def member : Parser[Any] = stringLit ~ ":" ~ value  
  def value : Parser[Any] = stringLit | numericLit | obj | arr |  
    "null" | "true" | "false"
```

44

Testing the JSON Parser

Add a method `main` that can be used to test the parser.

```
def main(args: Array[String]) {  
  val tokens = new lexical.Scanner(args(0))  
  println(args(0))  
  println(phrase(value)(tokens))  
}
```

Here are two test runs:

```
>java examples.parsing.JSON "{ \"x\": true, \"y\": [1, 2, 3] }"  
{ x: true, y: [1, 2, 3] }  
[1.26] parsed: ((({ ~ List(((x ~ : ) ~ true), ((y ~ : ) ~ (([ ~ List(1,  
2, 3)) ~ ]))) ~ }))) ~ }
```

45

```
>java examples.parsing.JSON "{ \"x\": true \"y\": [1, 2] }"  
{ x: true y: [1, 2] }  
[1.13] failure: unexpected token string literal y  
{ \"x\": true \"y\": [1, 2] }
```

46

Getting Better Output

- ▶ The result of the previous JSON parser was a tree containing all input tokens (in some not very legible form).
- ▶ We can get a more useful result by adding `^^` parts to the productions.

```
def obj : Parser[Any] = // return a Map  
  "{ \" ~> rep(member) <~ \" }" ^^ (ms => Map() ++ ms)  
def arr : Parser[Any] = // return a List  
  "[ \" ~> rep{value} <~ \" ]"  
def member : Parser[Any] = // return a name/value pair  
  stringLit ~ ":" ~ value ^^  
  { case name ~ ":" ~ value => (name, value) }
```

...

47

```
def value : Parser[Any] = (  
  obj  
  | arr  
  | stringLit  
  | numericLit ^^ (_toInt) // return an Int  
  | "null" ^^ null // return 'null'  
  | "true" ^^ true // return 'true'  
  | "false" ^^ false // return 'false'  
)
```

If we run the test now, we get:

```
>java examples.parsing.JSON1 "{ \"x\": true, \"y\": [1, 2, 3] }"  
{ x: true, y: [1, 2, 3] }  
[1.30] parsed: Map(x -> true, y -> List(1, 2, 3))
```

48

Table of Parser Combinators

ident	identifier
keyword(...)	keyword or special symbol (implicit)
numericLit	integer number
stringLit	string literal
P ~ Q	sequential composition
P <~ Q, P ~> Q	sequential composition; keep left/right only
P Q	alternative
opt(P)	option
rep(P)	repetition
repsep(P, Q)	interleaved repetition
P ^^ f	result conversion
P ^^ v	constant result

49

Arithmetic Expressions Again

Here is the full parser for arithmetic expressions:

```
object Arithmetic extends StandardTokenParsers {
  lexical.delimiters += List("(", ")", "+", "-", "*", "/")
  def expr: Parser[Any] = term ~ rep("+ ~ term | "-" ~ term)
  def term = factor ~ rep("* ~ factor | "/" ~ factor)
  def factor: Parser[Any] = "(" ~ expr ~ ")" | numericLit
```

Question: How can we make it evaluate the parsed expression?

50

A Problem with Top-Down Parsing

Because Parser Combinators work top-down, they do not allow left-recursion.

A production like

```
def expr = expr ~ "-" ~ term
```

would go into an infinite recursion when executed.

The alternative:

```
def expr = term ~ rep("- ~ term)
```

produces a "right-leaning" tree: $X - Y - Z$ parses

```
X ~ List("- ~ Y, "-" ~ Z)
```

But the correct reduction/evaluation of $+, -, *, /$ is left-leaning!

51

Evaluate by FoldLeft

We can solve this problem by delaying reduction until all elements of a repetition have been parsed and then performing a fold left on the list:

```
def expr : Parser[Int] =
  term ~ rep ("+" ~ term | "-" ~ term) ^^ reduceList
def term : Parser[Int] =
  factor ~ rep ("*" ~ factor | "/" ~ factor) ^^ reduceList
def factor: Parser[Int] =
  "(" ~> expr <~ ")" | numericLit ^^ (...toInt)
```

Here, `reduceList` is defined in terms of the fold-left operation `/:` ...

```
val reduceList: Expr ~ List[String ~ Expr] => Expr = {
  case i ~ ps => (i /: ps)(reduce)
}
```

52

... and `reduce` is defined as follows:

```
def reduce(x: Int, r: String ~ Int) = r match {  
  case "+" ~ y => x + y  
  case "-" ~ y => x - y  
  case "*" ~ y => x * y  
  case "/" ~ y => x / y  
  case _ => throw new MatchError("illegal case: "+r)  
}
```

With this, we get:

```
java examples.parsing.ArithmeticParsers1 "2 * (3 + 7)"  
2 * (3 + 7)  
[1.12] parsed: 20
```

53

Conclusion

- ▶ Combinator parsers give a provide a concise, flexible, and high-level way to construct parsers.
- ▶ The token classes of a context free grammar are modelled as primitive parsers.
- ▶ The combination forms are modelled as higher-order parsers.
- ▶ Combinator parsers are an example of an embedded DSL.
- ▶ By contrast, classical parser generators can be classified as stand-alone DSLs.
- ▶ Advantage of an embedded DSL over a parser generator: It's easier to connect the results of combinator parsers with the environment.
- ▶ Disadvantage: lower efficiency – but this can be overcome.

54
